

Supplementary Fig. 3. No significant changes of seizure recurrence rate (SRR) after 2 years of follow-up in sensitivity analyses. Sensitivity analyses of SRRs performed by removing each potential bias factor also showed results consistent with those of the primary meta-analysis. The SSR was 56.9% when excluding two studies that controlled antiseizure medication (ASM) use (A), and 59.3% when excluding two studies that controlled remote symptomatic cases (B). CI, confidence interval; FUS, first unprovoked seizure; FUS-S, FUS while sleeping.
