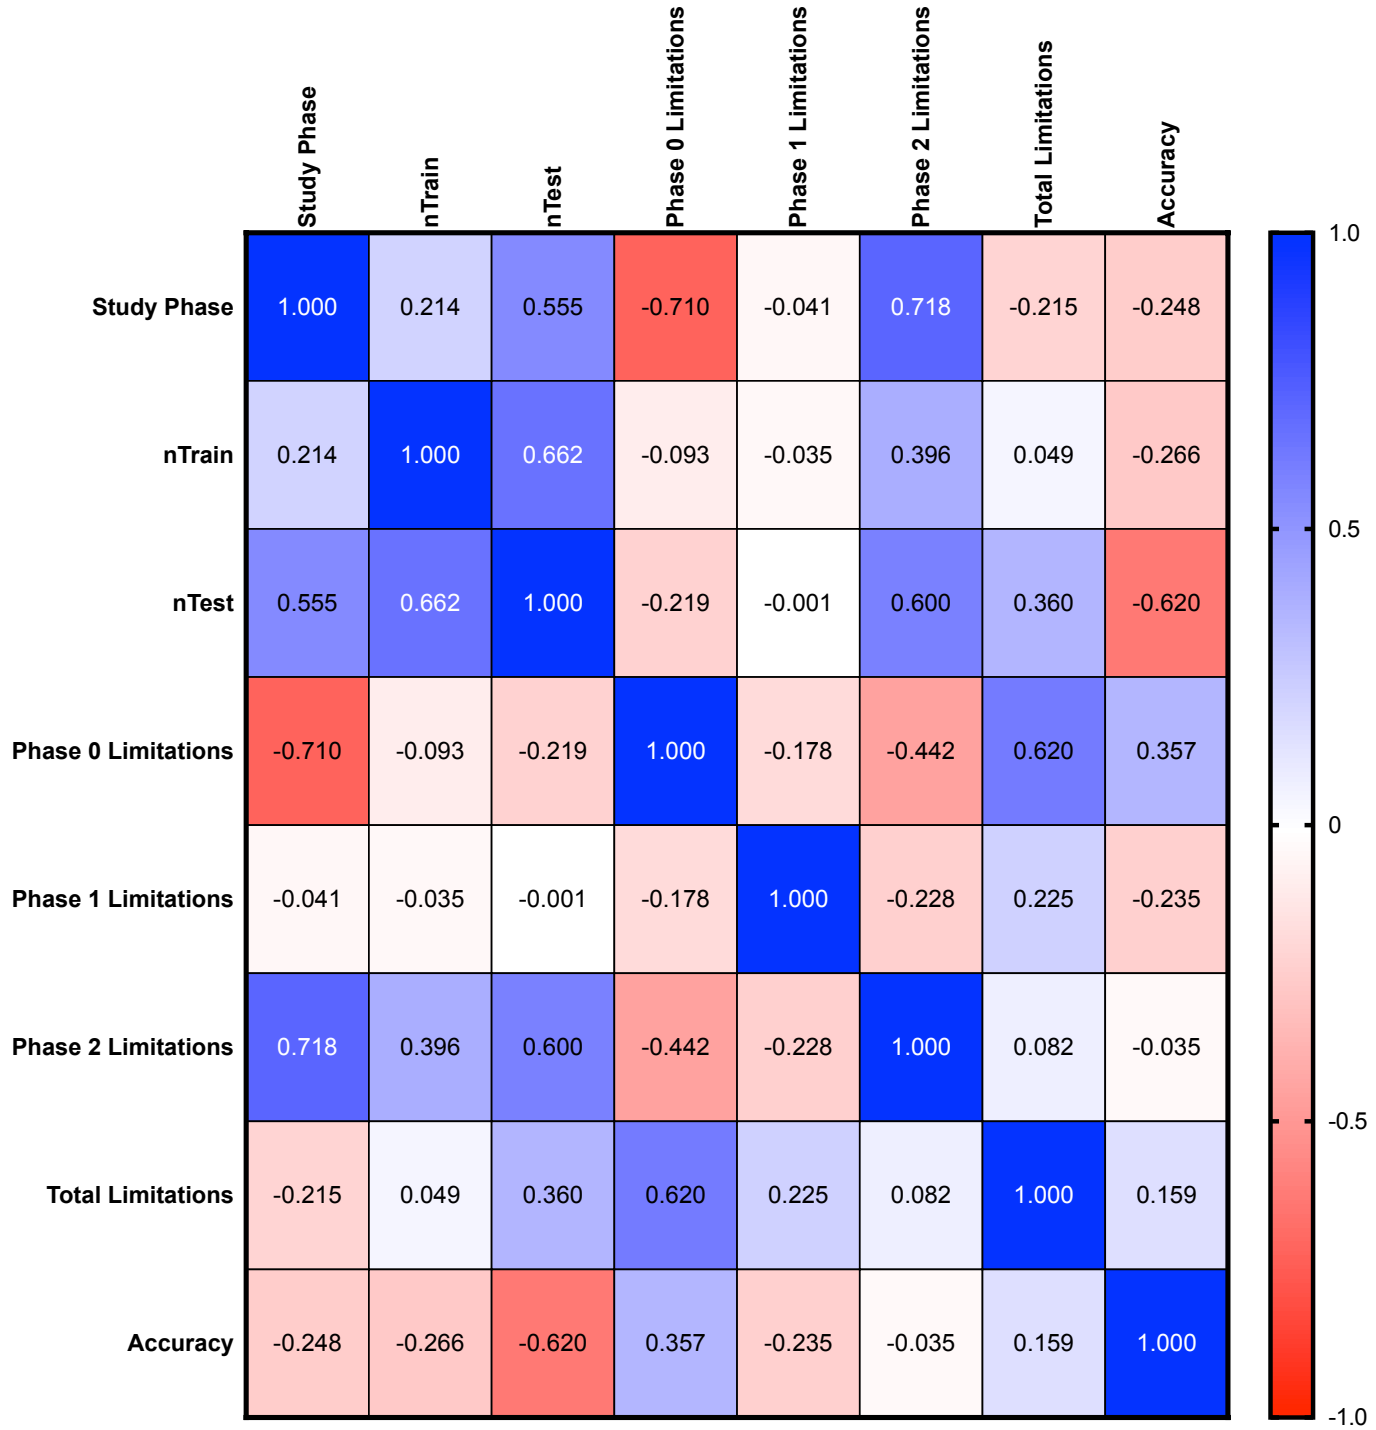
Supplemental Digital Content 8: Correlation of AI Study Characteristics



Supplemental Figure 3. Spearman r: Correlation of AI study characteristics. Values indicate the R values for AI algorithm characteristics: study phase, number of data points used for training (nTrain), number of data points used for testing (nTest), number of limitations as defined by study phase excluding phase 3 limitations (only one study had phase 3 limitations), total number of limitations, type of limitation (coded according to study phase as defined in the body of the text, and accuracy. Color represents the direction of the correlation: positive (blue) and negative (red). Saturation of the color represents the strength of the limitation. Characteristics were considered to have statistically significiantly non-zero correlations with p values <0.05. The nTest (p=0.008) and phase 0 limitations (p=0.03) were significantly associated with the primary outcome of accuracy. The nTest (p=0.025), phase 0 limitations (p<0.0001), phase 2 limitations (p<0.0001), and type of limitations (p<0.0001) were significantly associated with the other secondary outcome of study phase. Other statistically significant associations did not impact the primary and secondary outcomes.
