eAppendix 2. Computation of Price Elasticity of Demand

In this review, in addition to examining effect size estimates of outcomes for changes in demand (e.g., sales and consumption), we also convert each demand estimate into a common metric measure known as price elasticity of demand. The price elasticity of demand measure is calculated as a percentage change in demand (sales or consumption) over a percentage change in price. To estimate the price elasticity of demand for subsidized food products, percentage change in price was calculated for each subsidy assuming a 100% pass through, so that the price change was equal to the price discount (e.g., a 50% discount or rebate would correspond to a price change of -50%).

eTable 1. Quality Assessment of Fiscal Policy Studies

	Question	Scoring System (Yes = 1.0, Partial = 0.5, No = 0)
Control group	1. Does the study compare outcomes in an appropriate control group?	Yes = Control group (e.g., not impacted by policy) or counterfactual used.
		No = Uncontrolled study (no control group or counterfactual).
Measures	2. Does the study measure outcomes objectively?	Yes = Objective measures: sales (scanner data), purchases (receipts of purchases), prices (scanner data), measured body weight/height, health measurements (e.g., blood pressure), 24-hour dietary intake recall, government/ administrative records.
		Partial = Data recorded by raters or households, e.g., households recording purchases without receipts.
		No = Participant self-reported data: self-reported BMI, food frequency surveys, other surveys with self-reported data.
Follow Up	3. Does the study assess outcomes in the same people/ stores before and after the intervention?	Yes = Longitudinal design: same people/households/stores at baseline and follow-up.
		No = Not the same people/households/stores, e.g., repeated cross-sections or longitudinal data with high attrition rates (>25%).
Duration	4. How many data points does the study examine before and after the intervention?	Yes = The study has ≥3 data points before and after the intervention.
		Partial = The study meets the above criteria for either a pre- or post-intervention, but not both.
		No = The study has 1-2 observations per pre- and post-assessment.
Sample	5. Does the study use a representative sample of the population affected by the policy?	Yes = Representative data of the affected population, e.g., random population sampling.
		Partial = Somewhat representative of the affected population, includes scanner household consumer panels.
		No = Not fully representative or convenience sample, e.g., limited to only one store type or one chain, select list of products or brands or group of customers.
Sample	6. Does the study have a sufficient sample size?	Yes = Sample size or power analyses provided and shows sufficient sample size.
		No = No information provided or individual sample sizes appear insufficient; e.g., n<500 individuals per site/time period or store audits n<50 per site/time period.

© 2022 Andreyeva T et al. *JAMA Network Open.*

Confounding	7. Does the study adjust adequately for likely confounders?	Yes = If an ITS then it adjusted/removed the effect of existing time trends, seasonality, and economic fluctuations. If different people are in comparison groups, then also adjusts for demographic differences, such as age and socioeconomic status.
		Partial = Some of these factors were adjusted for.
		No = None of these factors were adjusted for.
Total Score: Sum scores on all measures (range 0 to 7) Low quality score ≤3.0 Medium quality score 3.5-4.5 High quality score ≥5.0

Abbreviations: INEGI, Mexico's Statistics Institute (*Instituto Nacional de Estadística y Geografía*, Spanish); BMI, body mass index; FA, food assistance; WIC, Special Supplemental Nutrition Assistance Program for Women, Infants, and Children; SNAP, Supplemental Nutrition Assistance Program; CBA, controlled before and after; ITS, interrupted time series; NCD, non-communicable disease; ENIGH, National Income and Expenditure Household Survey (in Spanish); BRFSS, Behavioral Risk Factor Surveillance System; UC, unintended consequences; EMIM, Monthly Survey of Manufacturing Industry.

Notes: An ITS design is defined as a study design that uses longitudinal data and has three or more post-treatment periods. An ITS was further classified as a controlled ITS, ITS with a counterfactual, and uncontrolled ITS. A controlled ITS used non-treated sites as a comparison; an ITS with a counterfactual used a counterfactual that was not untreated sites, for example, the pre-treatment trend or untaxed foods; an uncontrolled ITS did not have any type of comparison group. A before and after study used longitudinal data and made comparisons in two time periods: before and after tax implementation. Before and after studies were further classified as

© 2022 Andreyeva T et al. *JAMA Network Open.*

controlled before and after, and uncontrolled before and after. The criteria for these classifications are the same as for the ITS study designs.

[a] Not reporting #s of participants due to differences in the type of participants across studies (e.g., products, households, stores).
