Reviewer 3 v.2

Comments to the Author

The authors responded adequately to my questions except one. There is a difference between neutralizing anitobies enad total IgG. As far as I understand, the trials that are cited regarding antibodies, assessed total IgG by a ELISA test, i.e. without doing a neutralization test on COVID cultures. The authors should check this point in each trial and if it remains true that no trial assessed the neutralization capacity of the plasma, they should state it in the result and discuss it in the discussion sections. This is one of the reasons to promote trials of better quality, i.e. using a better calibrated product regarding its active component.
